Over-the-scope-clip: Endoscopic treatment of Boerhaave syndrome

Over-the-scope-clip: tratamiento endoscópico del síndrome de Boerhaave

M^a Henar Núñez Rodríguez*, Fátima Sánchez Martín, Rodrigo Nájera, Pilar Diez Redondo

Servicio de Aparato Digestivo, Hospital Universitario Rio Hortega, Valladolid, Spain

A 63-year-old man was admitted in Emergency Services 12 h after vomiting and hematemesis. He was on regular treatment with antihypertensive and anti-inflammatory. Haematocrit decreased from 43% to 30%. The patient had not got any sign of sepsis with a normal chest X-ray. Urgent gastroscopy demonstrated active haemorrhage due to a 10 mm oesophageal disruption located at the oesophagogastric junction (Fig. 1A). The procedure was performed at endoscopy room under deep sedation. The disruption was resolved with placement of over-the-scope clip (OTSC) (Fig. 1B). After that, the computer tomography discarded contrast leakage. The patient remained hemodynamically stable without haemorrhagic recurrence and

without fever during hospitalization. He was discharged home after 72 h. After 4 months of follow-up the patient remains asymptomatic. Endoscopic control demonstrated no clip at oesophageal mucosa (Fig. 1C).

Spontaneous oesophagus perforation (Boerhaave's syndrome) is a spontaneous disruption of the distal oesophagus associated with high mortality. Surgery repair during the first 24 h from perforation is the best option.¹ Surgery is associated with a high rate of mortality and morbidity. In the last years, endoscopic techniques have appeared²⁻⁴ to resolve gastrointestinal perforation. OTSC could be used for gastrointestinal perforation equal or under 10 mm.
