Abstract

Introduction: Gaining practical experience in health professions education is a significant challenge. Simulation-based training has emerged as a key solution to this issue, but the high costs associated with advanced equipment and software limit accessibility for many institutions. Hence, to close this gap, this study aims to map the research field of low-cost simulation in health professions education through a bibliometric analysis.

Methods: Utilizing a bibliometric study design, we analyzed publications from 2003 to 2022 in the Scopus Database, in accordance to Preferred Reporting Items for Systematic Reviews and Meta-Analyses 2020 guidelines. Publications discussing low-cost simulation in English were included. Data points such as research design, study location, and outcomes were extracted. The Scival Platform and VosViewer were used to analyze publication trends, prolific institutions, authors, journals, and conceptual and intellectual structure.

Results: The study found an increase in low-cost simulation research from 2003 to 2022, with significant growth after 2015. Observational studies predominated (68.57%), with general surgery being the most studied specialty. Less than half of the studies reported cost details, and only 2 compared the low-cost model with a standard. The United States led in scientific production, with notable collaboration networks. The keyword co-occurrence and co-citation analyses highlighted 4 main clusters in low-cost simulation research, emphasizing surgical training.

Conclusions: This investigation highlights the expanding interest in low-cost simulation to enhance access to hands-on training in health professions education, especially under financial constraints. However, the research field requires further development, particularly in validating...
these models against their more expensive counterparts. Such validation is crucial for ensuring the effectiveness and comparability of low-cost simulation.

Introduction

Health professions education faces a critical challenge: providing practical, hands-on experience in a safe environment. Simulation-based training offers a solution by bridging these gaps. However, the substantial costs of the necessary equipment and software present considerable obstacles for many institutions. These financial burdens undermine the quality of education and exacerbate inequalities, particularly impacting programs that are resource-constrained. Therefore, there is a need to develop a more accessible and equitable approach to simulation-based training.

Among a range of potential solutions, low-cost simulation is a feasible alternative. This method employs cost-effective materials to construct realistic training scenarios. Although previous studies confirm its effectiveness, research has focused on specific areas like urology, otorhinolaryngology, and general surgery. This narrow focus limits our comprehensive understanding of the field. Therefore, a more profound and extensive knowledge of low-cost simulations is essential to inform and guide future research initiatives.

To meet the identified need, we conducted a bibliometric analysis to map the research field of low-cost simulation (Concept) in health professions education (Context). This analysis documents and assesses foundational work, setting the stage for future studies and practical implementation. Moreover, the findings hold the potential to influence policy decisions and reduce disparities in health professions’ education quality.

Methods

A bibliometric study, a methodology that uses quantitative methods on bibliographic data, was conducted to analyze...
the research field of low-cost simulation in health professions education publications indexed in Scopus between 2003 and 2022. To enhance the replicability of our study, we followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 reporting guidelines, as done in previous bibliometric analyses in health professions education.

On October 11, 2023, a search was conducted in the Scopus Database using a strategy designed and reviewed collaboratively by two authors. The strategy was as follows: (TITLE-ABS-KEY(Low-fidelity) OR TITLE-ABS-KEY(low-cost) OR TITLE-ABS-KEY(homemade) OR TITLE-ABS-KEY(budget)) AND (INDEXTERMS("Simulation Training") OR TITLE-ABS-KEY(Simulation)).

The screening of titles and abstracts was performed in duplicate. Publications were included if they fulfilled the following criteria: (1) discussed the development, validation, or implementation of low-cost simulation and (2) were in English.

Then, for each study included, the following data points were extracted: (1) study aim, (2) study design, (3) comparison with a standard commercial model (if applicable) or indication of no model used for comparison, (4) medical specialty employing the low-cost simulation model (e.g., surgery, anesthesia, emergency medicine) with the specific task, and (5) reported cost of the low-cost simulation model.

Data analysis

We imported the list of identified studies to the Scival Platform (Elsevier). Within Scival and Biblioshiny, we identified key metrics to characterize the studies, including publication trends categorized by the Scopus quartile, the most prolific institutions, authors, and journals based on publication volume, and the most impactful publications regarding total citations. Then, we analyzed cross-country production and established co-occurrence networks through the bibliometrix package in R studio. After that, we conducted a co-authorship co-occurrence, keyword co-occurrence and co-citation analysis using the VosViewer platform to identify collaborations, intellectual and conceptual structure.

Results

Fig. 1 shows the overall growth of publication. The growth of studies published in low-cost simulation from 2005 (n=1) to 2022 (n=19). Scientific production did not experience significant growth before 2015. The year with the highest production was 2020, with even more publications in Scopus Quartile 1 journals.

Of the 105 studies included, 68.57% (n=72) were observational, 22.86% (n=24) were experimental, and 8.57% (n=9) were review articles as shown in Table 2. Of these, 96 articles had a comparison, with 94 (97.92%) not using a model and 2 (2.08%) comparing against the standard model. General surgery (27.08%) was the most predominant specialty where low-cost simulation was researched, followed by obstetrics and gynecology (14.58%), ear-nose and throat (12.5%), cardiovascular surgery (9.37%), and gastroenterology (6.25%). Less than half of the studies (45.84%) reported the cost of the models.

In Table 1, Simulation in Healthcare performed the best in terms of indicators, with 45 CT and 4 NP and a CiteScore 2022 of 3.4 (Q2). The International Journal of Gynecology and Obstetrics had the highest CiteScore 2022, ranking 5.7 in Q1. The five most productive authors’ research fields were general surgery and obstetrics. Furthermore, when applying...
Lotka’s law, 514 (94%) authors had only one publication in low-cost simulation. Additionally, 31 authors (5.7%) had 2 publications. However, only 2 authors (0.3%) had 3 publications. Moreover, all most impactful publication were in the surgical fields (see Table 3).

According to Fig. 2A, the United States (US) has the highest scientific production and is the center of collaboration networks in the field. The largest production in the field is in North America (US, Mexico, and Canada), with 40 studies. Fig. 2B shows a relationship between Ghanaian, Indian, and US production regarding collaboration networks.

We employ a keyword co-occurrence analysis (3A) and co-citation analysis (3B) to delve into the conceptual and intellectual structure. Fig. 3A identified 4 clusters: learning curve (yellow), surgical model development (red), simulation in surgery (blue), and simulation in obstetrics (green). In Fig. 3B, the co-citation analysis shows 4 clusters focused on developing the surgical model in the green, yellow, and blue clusters and the transferability of these models in the curriculum as shown in the red cluster. Therefore, this suggests that the field of low-cost simulation in health professions education is dominated by surgical simulation training.

**Discussion**

**Summary of findings**

We conducted a bibliometric study to delimit the scope of low-cost simulation research in health professions education. Our main findings are as follows: (1) The growth of studies published in low-cost simulation increased from 2005 to 2022, with the highest production in 2020. (2) Of the 105 studies included, 68.57% were observational, 22.86% were experimental, and 8.57% were review articles. (3) Less than half of studies reported the cost of models, and only two out of 96 studies compared the low-cost models with the standard ones. (4) The analyses showed that surgery was the main focus of study in low-cost simulation in health professions education.

**Strengths and limitations**

This study had several strengths, such as the peer-review process in all stages, a well-crafted research question, and the employment of both descriptive and analytical methods to study the field. Despite these strengths, it also presents some limitations. First, we only used the Scopus database, which, although previous research suggests that it covers the Medline database and is equal or superior to the Web of Science, may hinder our full understanding of the extension of the field. Second, the limited literature volume posed challenges for a more comprehensive analysis. However, to surpass this limitation, we extracted key datapoints from identified studies such as comparator models or costs. Hence, adding relevant information to our study. Lastly, we did not analyze quality or bias among studies as it was out of the scope of a bibliometric and due to the lack of a checklist to assess low-cost simulation studies.

**Interpretation of findings**

To our knowledge, this is the first bibliometric study on low-cost simulation for health professions education. The growth of research from 2015 underscores the need for viable solution to bring equitable access to health professions education.

- Most participants value the simulation with papayas as highly beneficial and that it would change their clinical management
education, as was described in previous studies. While noble, it is of importance to notice that less than 1% of the identified studies compare the low-cost models with standard models. This raises a concern regarding the validity of these models, a finding similar to previous reviews in low-cost simulation.

Although disappointing, these findings reflect the novelty of the topic and set a future direction for research in the field, being one of the major concerns—the validity of low-cost simulation.

Contrary to what we expected, the global south was underrepresented in the field, which is aligned with a previous systematic review. This underscores a well-described gap in health professions education literature, that may be explained due to lack of funding, deficits in faculty capacity, or time protected for research. These potential barriers hinder the potential that low-cost simulation may offer for low-resource countries. Hence, policy- and decision-makers should take this into account for further development in simulation training.

Most of the research was conducted in the surgical field. This is in accordance to previous systematic reviews focused on surgery, ear-nose and throat, and urology. This may be explained due to that low-cost simulation may pose as a feasible option for implementing mastery learning in health professions education, specifically for skills-acquisition. In this context, trainees could develop low-cost models for specific procedures such as laparoscopic simulator or an amniocentesis model for home training. To exemplify this, employing a low-cost models for amniocentesis, Ramirez-Abarca et al. were able to determine the number of procedures to attain competency in maternal–fetal medicine fellows, which was 255 procedures, something that may be not attainable in standard models. Hence, to our understanding, the true potential of low-cost simulation is in
Fig. 3  Conceptual (3A) and intellectual structure (3B) in the research field of low-cost simulation in health professions education from 2003 to 2022 in the Scopus database.
its integration with mastery learning and for skills-acquisition. Thus, future research should address the learning curve of essential procedures employing low-cost models and may expand towards low-cost simulations models for task such as history taking, physical examination or communication training.

Conclusions

In conclusion, research on low-cost simulation has increased recently, but its quality needs to be addressed. Most studies were observational with lack of standard comparators. As a result, most of the studies reported model that need to be validated at different levels of education. However, these low-cost models has the potential to help medical schools reduce future costs and increase competency in simulation-based learning.
