Surgical Treatment of Supraclavicular and Internal Mammary Recurrence of Breast Cancer
Tratamiento quirúrgico de la recidiva supraclavicular y a nivel de la mamaria interna por un carcinoma de mama

Brito et al. treated patients with supraclavicular lymph node involvement using multimodal therapy with curative intent (chemotherapy [CTx], surgery and radiotherapy). With this method, they obtained better results than in patients who presented distant disease that was not supraclavicular. These results led to the review and modifications of the American Joint Committee on Cancer (AJCC-TNM) classification. Since its sixth edition, metastases in the ipsilateral supraclavicular lymph nodes have ceased to be considered distant metastases (M1) and have been classified as locoregional disease (N3c). To this day, the debate continues and no consensus has been reached for the treatment of these patients.

Likewise, contralateral axillary involvement should be considered stage IV and therefore the treatment of these patients should be palliative. However, there is a hypothesis that dissemination to the contralateral axilla could occur by the lymphatic pathway, therefore locoregional curative treatment would be justified. Therefore, the management of this situation is not standardized and must be individualized for each patient.

We present a controversial clinical case using multimodal treatment, associating surgery of a metastatic breast carcinoma with contralateral and ipsilateral supraclavicular lymph nodes.

A 57-year-old woman presented with a 10 cm ulcerated tumor infiltrating the skin and chest wall of the right breast. Mammography, magnetic resonance imaging with gadolinium contrast and core-needle biopsy diagnosed the mass as invasive ductal carcinoma (IDC) of the right breast with ipsilateral and contralateral axillary lymph node involvement (cT4c cN1c M1). Immunohistochemistry study reported: estrogen receptors (ER) +++, progesterone receptors (PR) +, c erbB2 + (positive FISH), Ki 67 20%.

After 8 cycles of CTx with docetaxel, trastuzumab and pertuzumab with good radiological response, radical mastectomy was performed with right and left axillary lymph node dissection. The pathology study of the piece reported an...
In metabolism, measuring macroscopic month decrease treatment axillary defect mammary (trastuzumab mammary 67 mammary (trastuzumab mammary grade study. one in cycles measuring with metabolism the 2 1.5 emtansine) 2.1, measuring by and right lymph node involvement: the same in 1.5 metastasis measuring 5×1.6 cm, with involvement of soft tissues (striated muscle and fibrous-fatty tissue) by lobular carcinoma, with no bone involvement, free resection margins and immunohistochemistry: RE –, RP –, cerbB2 –, Ki 67 5%–10%. From the cervical lymph node dissection, 52 lymphadenopathies were isolated with no tumor involvement. The patient currently continues with adjuvant CTx with TDM1 and is disease-free 9 months after the intervention.

There are numerous publications that evaluate the results of radiotherapy in the involvement of the internal and supraclavicular mammary arteries; however, the role of surgery has not yet been studied. In the review of the literature, there is a study that included patients with recurrence of the disease at the supraclavicular level where surgery was part of the treatment and concluded that surgical excision of these supraclavicular lymph nodes would be a prognostic factor for overall survival.

The negative pathology results of the lymph nodes removed in the cervical lymphadenectomy could be explained by a complete response to CTx that was already evident in the re-evaluation PET after the end of the last cycle, where there was a decrease in metabolic activity.

Although locoregional therapy is not standard in the treatment of de novo stage IV cancers, it is usually used as a palliative treatment. In this group of patients, this would be the case by including surgery in multimodal treatment for better control of the disease. There are authors who defend that patients with advanced tumor disease and certain cancer subtypes, such as luminal-like or Her2, can be offered local treatment with surgery or radiotherapy when this means better control of the primary tumor or the regional involvement in order to improve overall survival. In cases in which radiotherapy cannot be applied, as in our patient, surgery would be the option for better locoregional control of the disease.

Ileocolic Intussusception by Appendicular Mucocele

Intususcepción ileocólica por mucocele apendicular

Appendiceal intussusception is a rare pathology. It represents only 0.01% of indications for appendectomy¹ and is a diagnostic challenge.²

We present the case of a 20-year-old female patient who came to the Emergency Room with colicky abdominal pain in the right iliac fossa that had lasted for several days, with no other associated symptoms. Blood work-up showed no alterations. Due to the persistence of the pain, imaging tests were indicated. Ultrasound revealed an image in the right iliac fossa. A CT scan showed a tubular structure with hypodense content at the hepatic angle that ended in a cecal sac (Fig. 1), as well as the invagination of the terminal ileum and the ileocecal valve in the right colon (Fig. 2). The findings were compatible with the diagnosis of invagination of an appendiceal mucocele, therefore urgent laparoscopic ileocectomy was performed. The postoperative evolution was favorable, and the patient was discharged from hospital on the third postoperative day. The pathology study reported an appendiceal mucocele with no malignant histological features whose base protruded into the lumen of the cecum, causing intussusception.

Appendiceal intussusception is defined as the invagination of a portion of the appendix into its own lumen or that of the cecum. It is secondary to abnormal peristaltic movements caused by inflammation of the appendix and favored by lax mesoappendices with a broad appendicular lumen or by very mobile and thin appendices.³ This pathology appears more frequently in adults (76%) than in children, and in women than in men, with a 2:1 ratio. The most frequent age at onset is the fourth decade of life.² In pediatric patients, the most frequent cause is inflammation of the appendix, while in adults the most common etiology is endometriosis (33%) followed by appendiceal mucocele (19%) and appendiceal inflammation (19%). In the remaining cases, the etiology is tumors and there have been descriptions of carcinoid tumors, metastasis, hamartomas or lymphomas.²,⁴,⁵
