scientific, pragmatic, economic, and legal reasons to grant the MMSE an honourable retirement in light of its nearly 40 years of dedicated service. I can only cite sentimental reasons for continuing to recommend this questionnaire.

Conflicts of interest

There is no scientific basis for retiring the MMSE\(^\text{c}\)**

No hay razones científicas para jubilar al MMSE

Dear Editor:

The article by Carnero-Pardo published in Neurología\(^\text{1}\) has revived the debate on the possible obsolescence of the Mini-Mental State Examination (MMSE).\(^\text{2}\) In his review article, the author advocates retiring the MMSE and argues that there are other tests which are shorter and more effective for detecting cognitive impairment. We feel that Dr Carnero-Pardo’s arguments are biased by the lack of time faced by clinicians in Spain as well as by other specific circumstances.

The 4 arguments the author uses to support the ‘well-deserved retirement’ of the MMSE are the lack of standardisation for its items, the effect of socio-educational variables on results, its limited effectiveness for detecting cognitive impairment, and the fact that it is copyright-protected. At present, however, these arguments lack the scientific basis necessary to be considered valid, for several reasons.

(1) It is quite true that some items (words to be memorised, phrases to repeat, etc.) vary between versions and that a more uniform administration process would be helpful. Nevertheless, what defines a test’s construct validity (and general validity) is the extent to which each item assesses what the test claims to assess. This has been demonstrated repeatedly in the case of the MMSE.\(^\text{3,4}\) In Spain, the version translated by Tolosa et al.\(^\text{5}\) and the version validated by the NORMACODEM group\(^\text{6}\) are almost identical, and very similar to the original MMSE. These, along with the Mini-Examen Cognoscitivo (MEC, the first adaptation of the MMSE in Spain) are the most widely-used versions. The latest 30-point version of the MEC is more similar to the original MMSE, which indicates a progressive standardisation process.\(^\text{7}\)

(2) The MMSE is sensitive to sociodemographic variables. This is also true for most cognitive tests, although in varying degrees: the clock drawing test, for example, is more affected by these variables. The effectiveness of the MMSE is known to be lower among Spanish speakers

Table 1 Examples of responses to the writing item on the MMSE, corrected according to different criteria.
than among English speakers. Likewise, sex, age, educational level (<9 years of education), and especially illiteracy limit its effectiveness for assessing cognitive impairment and detecting dementia. Illiteracy, however, does not seem to affect performance when the cut-off point is lowered, as Carnero-Pardo himself shows diagnostic utility of 0.86 in a sample in which illiterate individuals constituted 14.3%. Another option would be to modify those items sensitive to illiteracy or a low educational level, as one study did to assess cognitive impairment in an Asian population, or to include functional assessment scales with good sensitivity and high specificity for dementia screening. Both of these strategies were used in the NEDICES study. Furthermore, it is commonly accepted that people with severe limitations for completing cognitive evaluations (hearing or visual impairment, illiteracy) must be thoroughly assessed using ad hoc tools.

(3) As Carnero-Pardo correctly states, cognitive impairment (whether mild cognitive impairment or dementia) is the sole target to be detected, but his view on the utility of the MMSE is erroneous. The sensitivity and specificity values that he mentions, taken from a meta-analysis, do not correspond to subjects with cognitive impairment but to subjects with mild cognitive impairment. The data he presents, which supposedly favour the Fototest, are biased since he did not use the optimal cut-off point for the MMSE. Comparative data from the Fototest and other short cognitive tests show similar diagnostic performance when the optimal cut-off points are applied (Table 1).

(4) As far as we are concerned, the copyright of the MMSE is only applicable to the original English version of the questionnaire and to validated and registered ad hoc versions in other languages and only in such cases in which they are used for potentially lucrative economic activities (clinical trials, among others). It seems highly unlikely that researchers would have to pay copyright fees in any other than the circumstances described above especially since public healthcare is a non-profit field, and considering that we do not use the original version. To the best of our knowledge, no lawsuits have ever been brought for using the MMSE in the contexts we have mentioned (even when results are subsequently published).

As previously stated and as shown in Carnero-Pardo’s well-chosen figure, the MMSE has become a standard tool for assessing cognitive function, especially in the elderly (nearly 30000 hits on PubMed in 2012). This is the case because the test now exists in so many languages and countries, and because of its versatility, which has given rise to multiple versions: short versions, long versions (3 MS), telephone versions, and versions adapted to specific populations (MMSE-37). Standard tools should not be retired; at most, they might be replaced by better tools, but there is no consensus as to which tool is better than this one. As such, there is no scientific basis for retiring the MMSE, although adaptations for specific populations or studies have already been made and are certainly welcome. While better cognitive assessment tools may be available in the future, the MMSE is the most widely accepted option to date.

Reflections on endovascular treatment for ischaemic stroke. A stroke care plan for the Region of Madrid

Reflexiones sobre el tratamiento endovascular en el ictus isquémico agudo. Plan de atención al ictus en la Comunidad de Madrid

Dear Editor:

We are pleased that our study, ‘Reflections on endovascular treatment for ischaemic stroke. A stroke care plan for the Region of Madrid’, has generated the interest expressed in this letter, which raises the possibility of establishing criteria for defining, from the very beginning, which stroke patients are candidates for endovascular treatment. These patients would therefore be transferred directly to the on-call reference hospital with no other unnecessary transfers.

We fully agree that proper identification of candidates will contribute to reducing treatment delays. Nevertheless, we believe that the current system now achieves a good balance between effectiveness and optimal use of resources.

First of all, all patients with stroke, and particularly those who may be candidates for specific treatment, must be assessed in centres with all the necessary resources to provide an exact diagnosis and indicate the appropriate treatment. The right actions carried out by non-hospital emergency medical services are crucial in order to stabilise patients and transfer them to the hospital as quickly and in the best condition as possible. Nevertheless, these services are not able to identify candidates for endovascular treatment with sufficient precision given the means at their disposal. This intervention is indicated based on strict criteria and expert assessment, after which only a small percentage of all stroke patients will be determined eligible to undergo endovascular treatment. Sending patients who have not received this initial screening to hospitals of reference for treatment would saturate them with patients who, for the most part, would not be candidates for the procedure. This would make the system less efficient. The 2014 update to the Region of Madrid’s Stroke Care Plan has improved the system with the addition of the ‘neurologist-case manager’. The effect of this addition is that as soon as the emergency services make contact with the neurologist to activate code stroke, the doctor can then determine if the patient is not a candidate for intravenous thrombolysis but may benefit from endovascular treatment. In that case, the neurologist will contact the reference hospital for neurointerventional surgery to address immediate transfer of the patient.

On the other hand, the treatment shown to be the most effective in patients with ischaemic stroke is care in a stroke unit and intravenous thrombolysis in selected cases. The Region of Madrid’s Stroke Care Plan ensures that all patients with stroke in our area will have rapid access to these resources, regardless of place of residence, by means of a code stroke system to facilitate emergency patient transfers to the nearest stroke units. This system is under the very effective management of the Madrid emergency medical responders (SUMMA/SAMUR), and it has yielded excellent results with regard to both the number of patients treated and the number of good outcomes. Endovascular treatment may be an alternative for some patients who are not candidates for or do not respond to standard treatment, but it has
